Abstract: The pollen morphology of 13 species belonging to the 3 genera of the family Geraniaceae was investigated with a light microscope and scanning microscope. It is eurypalynous in nature. Pollen grains mostly oblate-spheroidal, rarely prolate-spheroidal or spheroidal, often sub-oblate. Tectum reticulate with dense beculae or gammate muri, or striate. On the basis of exine ornamentation and apertural types, 3 distinct pollen types were recognized viz., Erodium cicutarium-type, Geranium himalayense-type and Monsonia senegalensis-type.

Key Words: Pollen morphology, Geraniaceae, Pakistan

Introduction

Geraniaceae is represented by 5 genera and c. 750 species, is cosmopolitan in distribution, but is mostly in temperate areas [1, 2]. In Pakistan it is represented by 4 genera and c. 26 native species [3]. The family is divided into two tribes i.e., Geranieae (Geranium L., Erodium L., Monsonia L. and Sarcocole) and Pelargonieae (Pelargonium L. Herit ex Aiton) by Hutchinson [4]. Bortenschlager [5] studied the pollen morphology of the family Geraniaceae in relation to taxonomy. Oltmann [6] described the pollen morphology of the order Geraniales. El-Oqlah [7] examined the pollen grains of the genus Erodium L. from Middle East. Similarly, Verhoeven & Venter [8] studied the pollen morphology of the genus Erodium L. from south Africa.

The pollen morphology of the family has been studied by many researchers such as Selling [9], Heusser [10], Erdtman [11], Kuprianova and Alyoshina [12], and Moore and Webb [13]. There are no reports on the pollen morphology of the family Geraniaceae from Pakistan. In the present paper, the pollen morphology of 3 genera distributed in 16 species of the family Geraniaceae was examined with a light and scanning electron microscope.

Materials and Method

Pollen samples were obtained from Karachi University Herbarium (KUH) or collected from the field. The list of voucher specimens is deposited in KUH. The pollen grains were prepared for light (LM) and scanning microscopy (SEM) by the standard methods described by Erdtman [11]. For light microscopy, the pollen grains were mounted in unstained glycerine jelly and observations were made with a Nikon Type-2 microscope, under E40, 0.65 and oil immersion (E100, 1.25), with a 10x eye piece. For SEM studies, pollen grains were suspended in a drop of water and directly transferred with a fine pipette to a metallic stub using double-sided cellotape and coated with gold in a sputtering chamber (Ion-sputter JFC-1100). Coating was restricted to 150A. The S.E.M examination was carried out on a Jeol microscope JSM-T200. The measurements were based on 15-20 readings from each specimen. Pollen diameter, polar axis (P) and equatorial diameter (E), colpi length, apocolpium, mesocolpium and exine thickness were measured (Tables 1-2).

The terminology used is in accordance with Erdtman [11]; Kremp [14]; Faegri and Iversen [15] and Walker and Doyle [16].

**Observations**

**General pollen characters of the family Geraniaceae**

Pollen grains usually radially symmetrical, isopolar, generally oblate-spheroidal, rarely sub-oblate, trioblate, fossaperturate, tricolporate, colpi short, sexine thicker than nexine. Tectum reticulate with densely baculate or reticulate baculate or reticulate. On the basis of exine ornamentation and apertural types 3 distinct pollen types are recognized viz. *Geranium himalayense* - type, *Erodium cicutarium* - type, *Monsonia senegalensis* - type Pollen type I: *Erodium cicutarium* -type (Fig. 1 A-E: Fig. "C and D).

**Pollen class**: Tricolporate

**P/E ratio**: Subtransverse, rarely semi-transverse.

**Shape**: Oblate-spheroidal, rarely sub-oblate.

**Apertures**: Ectoaperture-colpi small, or large and circular.

264
Exine: Sexine thicker than nexine, or as thick as nexine.

Ornamentation: Tectum coarsely reticulate with baculate or gemmate muri, muri with striation.

Measurements: Polar length (P) 43.7 (29.4±0.13) 89.4 μm, Equatorial diameter (E) 43.81 (29.75±1.41) 89.40 μm, colpi 10.18 (5.35±1.94) 35.9 μm in diameter. Mesocolpium 35.9 (18.54±0.22) 68.21 μm. Apocolpium 17.9 (18.54±0.36) 35.21 μm. Exine 5.31 (1.57±0.19) 10.71 μm thick.

Species included:

- **Erodium oxyrrhynchum** M. Bieb. ssp. oxyrrhynchum,
- **E. oxyrrhynchum** M. Bieb. subsp. bryoniifolium (Boiss.) Sch. –Tem., **E. malacoides** (L.) L’Herit ex Aiton.,
- **E. laciniatum** (Cav.) Willd ssp. pulverulentum (Cav.) Burtt & Lewis, **E. cicutarium** (L.) L’Herit ex Aiton.

Species included: Monsonia senegalensis Guill.&Perr.

Discussion
Geraniaceae is a eurypalynous family [11]. The pollen morphology of the family is significantly useful at the generic level.

The pollen grains are usually radially symmetrical, isopolar, generally oblate-spheroidal, rarely sub-oblate, trilobed, tricolporate, rarely colpate, colpi short, sexine thicker than nexine. Tectum reticulate with densely baculate or gemmate muri or striate. The palynology of three genera i.e., Monsonia L., Erodium L. and Geranium L., was examined. Taxonomically these genera are closely related (separated on the basis of number of fertile stamens, leaf type and stylar axis). Palynological data also correlates to the above taxonomical interpretation of the family and each genus has more or less its own characteristic pollen type.

On the basis of exine ornamentation and apertural type 3 distinct pollen types were recognized viz. Geranium himalayense -type, Erodium cicutarium -type, Monsonia senegalensis -type.

Pollen type-I is characterized by a simple striate tectum. Verhoeven and Venter [8] reported a similar pollen type in Erodium L. (except Erodium oxyrrhynchum ssp. oxyrrhynca striate-reticulate tectum with gemmate and baculate muri). Bortenschlager [5] examined 33 Erodium L. species and recognized two basic types namely, Geranium multiflorum and Erodium L. El-Oqlah [7] also identified the two basic pollen types in Erodium L. The shape and size and apertural type of the grain do not show much variation, throughout the pollen type.

Pollen type-II is readily distinguished by a reticulate-striate tectum which is heavily ornamented with baccula and gemmae. Erdtman [11] described similar a type of pollen in the genus Geranium L., 9 species viz., Geranium lucidum L., G. robertianum L., G. ocellatum Camb., G. rotundifolium Lindl., G. nepalense Sweet G. wallichianum D. Don ex Sweet, G. himalayense Kl., G. collinum Steph ex Wild., G. swatense Schonbeck-Temesy, have been studied from this genus. However, species of Geranium L., show little variation in their shape, size, mesocolpium and exine ornamentation which are significantly helpful for characterizing the species into one group viz., Geranium ocellatum -group and five species Geranium lucidum L., G. nepalense Sweet G. wallichianum D. Don ex Sweet, G. himalayense Kl., G. collinum Steph ex Willd. (see the tey to the species and species group).

Pollen type-III is easily recognized by its colpate pollen with very coarsely reticulate tectum. Only a single species Monsonia senegalensis Guill. & Perr., is included in this pollen type. Venter [17] also reported a similar type of pollen in the genus Monsonia L.
