Abstract: The asymmetric synthesis of $\alpha$-(heteroaryl)alkylamines was accomplished by employing a diastereoselective nucleophilic 1,2-addition of lithiated aromatic heterocycles to aldehyde SAMP-hydrazones, followed by BH$_3$-THF or SmI$_2$ promoted removal of the chiral auxiliary. The CBz or benzoyl-protected amines were obtained in good yields (40%–78%) and excellent enantiomeric excesses ($ee = 88$%–99%). The methodology can be applied to the synthesis of highly enantioenriched $\alpha$-amino acids ($ee = 90$%–99%).

Key words: Amines, asymmetric synthesis, SAMP-hydrazone, nucleophilic addition, amino acids

1. Introduction

Highly enantiomerically enriched amines with a stereocenter in the $\alpha$ position are of paramount importance in organic chemistry.1 In particular, $\alpha$-(heteroaryl)alkylamines are often characteristic structural features of biologically active natural products and pharmaceuticals. For example, $\alpha$-(2-furyl)alkylamines constitute the backbone of numhar alkaloids, $\alpha$-(3-pyridyl)alkylamines are common subunits in the tobacco alkaloids, and the potent antineoplastic agents dolastatin 102 and virenamides3 are both linear peptides containing $\alpha$-(2-thiazolyl)ethylamine units (Figure 1). From a synthetic point of view, $\alpha$-(heteroaryl)alkylamines are widely used as chiral ligands in metal complex catalysis4 and as important starting materials. Particular attention has been focused on the various synthetic applications of $\alpha$-(2-furyl)alkylamines. Oxidative cleavage of the furan ring under mild conditions allows the conversion into $\alpha$-amino acids.5 Moreover, the aza-Achmatovicz rearrangement6 represents an easy and unique entry into the piperidine skeleton and has thus been applied in the synthesis of numerous alkaloids7 and azasugars.8

The broad utility of $\alpha$-(heteroaryl)alkylamine derivatives has stimulated a relentless pursuit of practical asymmetric routes to these valuable compounds. Since the pioneering work by Smith and co-workers,9 which was based on classical resolution of the racemate with an optically active acid, there has been significant growth in this area and thus many reliable synthetic methods have been devised. To date, most approaches have been based on a nucleophilic attack of organometallic reagents on imines bearing a stereogenic $N$-substituent. Savoia et al. applied valine derivatives as chiral auxiliary in the asymmetric synthesis of $(S)$-1-(2-pyridyl)alkyl-amines. Although $(S)$-valinate10 gave good results, $O$-trimethylsilyl valinol11 proved to be a superior chiral auxiliary affording high yields and excellent diastereoselectivity ($de = 40$%–99%).

Figure 1. Typical biologically active compounds containing α-(heteroaryl)alkylamine units.

Zhou et al.\textsuperscript{12} explored the addition of cerium derivatives to chiral imines derived by condensation of 2-furaldehyde and (1\textit{S},2\textit{R})-2-amino-1,2-diphenylethanol or its enantiomer (\textit{de} = 84\%–99\%). Harwood and co-workers\textsuperscript{13} used (\textit{S})-5-phenylmorpholin-2-one in the presence of a range of aliphatic aldehydes to form enantioenriched iminium intermediates, which underwent diastereoselective Mannich reactions with 2-furylboric acid to afford the corresponding tertiary amines in moderate to good yields and high diastereoselectivities (\textit{de} = 86\%–98\%). On the other hand, chiral oxime ethers were employed by Moody et al.\textsuperscript{14} in an asymmetric synthesis of \textit{N}-protected 1-(2-thiazolyl)alkylamines (\textit{ee} = 83\%–92\%). More recently, a few cases have been reported using asymmetric catalytic nucleophilic 1,2-additions.\textsuperscript{15} A conceptually different approach was presented by Shiori et al.\textsuperscript{16} investigating the \textit{α}-alkylation of chiral Schiff bases obtained by condensation of 1-(2-heteroaryl)methylamine and (+)-2-hydroxy-3-pinanone or (-)-3-hydroxy-2-caranone. The method was extremely efficient when pyridine and furan moieties were used, and after removal of the chiral auxiliary the corresponding amines were obtained in excellent enantioselectivities (\textit{ee} = 88\%–98\%). Demir et al.\textsuperscript{5a,d} studied the reduction of furyl ketone oxime ethers using chiral boron reagents\textsuperscript{17} prepared from optically pure amino alcohol and BH\textsubscript{3}-THF complex (\textit{ee} = 87\%–95\%). Finally enzymatic\textsuperscript{18} and chemical\textsuperscript{19} resolution of racemic amines have been employed as well by different groups.

\textit{HetAr} = various hetarenes

We have briefly reported a very efficient asymmetric synthesis of α-(heteroaryl)alkylamines\textsuperscript{20} by nucleophilic 1,2-addition of metallated hetarenes to aldehyde-SAMP-hydrazone. Herein we disclose the full account of this research and further applications of this protocol to the synthesis of α-amino acids.

Our general protocol exploring the use of easily accessible lithium hetarenes is depicted in Scheme 1. Preliminary studies were conducted treating the simple propanal-SAMP-hydrazone 2a, dissolved in THF or alternatively in Et\textsubscript{2}O, with 11 different lithiated heterocycles\textsuperscript{21} prepared by modified literature procedures.\textsuperscript{22} Due to the different nature, basicity, and reactivity of the hetarenyllithium species, optimal reaction conditions
had to be determined case by case. We found that either 2- or 3-thienyllithium (Table 1, Entries 1 and 2) reacted well using Et₂O as solvent. The highest conversions and selectivities were obtained by treating hydrazone 2a with 3 equiv of organolithium compound at −78 °C for 30 min, after which the reactions were allowed to warm up to room temperature. The NMR spectra of the crude products showed only the desired hydrazines without the presence of starting material or eventual side products.

**Table 1.** Nucleophilic 1,2-addition of lithiated hetarenes to 2a to form the hydrazines 3a-k (Scheme 1).

* Yield of crude product (≥95% purity as determined by ¹H and ¹³C NMR spectroscopy).

*² Determined by ¹H and ¹³C NMR spectroscopy.

*³ Conversion (determined by ¹H and ¹³C NMR spectroscopy).
The reactions turned out to be very efficient, even if a chloride atom was carried on the thiophene ring (Entry 3), affording the corresponding hydrazine in excellent yield as a single product. 2-(Pyridinyl)lithium and 3-(pyridinyl)lithium (Entries 5 and 6) showed the highest reactivities and thus a relatively high instability. Therefore, the reactions were carried out at low temperature and 8 and 5 equiv of organolithium species had to be used, respectively. It was noteworthy that employing THF as solvent in all the previous cases changed drastically the reactivity of the lithium hetarenes, affording only traces of products. On the other hand, THF was clearly a superior solvent in the cases of 1-methyl-2-lithiumpyrrole (Entry 4), 1-methyl-2-lithio-indole (Entry 7), 1-methyl-2-lithio-imidazole (Entry 8), and 1-methyl-2-lithio-benzoimidazole (Entry 9), providing excellent diastereoselectivities when the reactions were allowed to reach room temperature overnight. Finally, 1,2-nucleophilic addition using 2-(furyl)lithium (Entry 10) and 2-(benzofuryl)lithium (Entry 11) was conducted in THF for the former and in Et₂O for the latter.

Due to the sensitivity of the obtained hydrazines, cleavage of the chiral auxiliary was performed using the crude products without any purification. We were pleased to find that the chiral auxiliary group could be removed smoothly without detectable racemization when hydrazines 3a–d were refluxed with a large excess of BH₃•THF complex for 6–18 h. The corresponding polar amines were not isolated but directly treated with CbzCl to give the corresponding carbamates 4a–d, which could be purified by flash chromatography on silica gel (Table 2). Unfortunately, when the hydrazines 3e–k were reacted with an excess of BH₃•THF only poor results were obtained. Attempts to overcome the problem using Zn in acetic acid met the same fate. In an effort to find a suitable method for removing the chiral auxiliary, we decided to examine the SmI₂ promoted N-N bond cleavage. For this purpose, the tertiary hydrazines had to be activated by conversion to the corresponding benzoyl derivatives. The desired reaction was performed treating 3e–k with an excess of benzoyl chloride in the presence of a stoichiometric amount of Et₃N and a catalytic amount of DMAP. The obtained N-benzoyl hydrazines could be isolated after purification as a mixture of amide rotamers in high yields. We were delighted to find that when treating the N-protected hydrazines with 2–3 equiv of SmI₂ in the presence of an equimolar

Figure 2. X-ray crystal structure and absolute configuration of 4l and proposed mechanism for the nucleophilic 1,2-addition of lithiated heteroarenes to the aldehyde-SAMP-hydrazones.
amount of DMPU a smooth cleavage of the chiral auxiliary took place. After purification, the corresponding benzoyl amines 4–k (Table 2) were obtained in a very good overall yield. Furthermore, determination of the ee value by HPLC analysis using a chiral stationary phase by comparison with the racemate showed that the cleavage proceeded without any detectable epimerization or racemization.

a Yield of isolated product over 2 steps.
b Determined by HPLC on a chiral stationary phase.
c Determined by GC on a chiral stationary phase.

The absolute configuration of the protected amines 4 was determined to be S by single crystal X-ray analysis (Figure 2, A)²⁵ on the N-acetyl protected 1-(thiophen-2-yl)propan-1-amine synthesized according to an analogous procedure (see Experimental). This stereochemical outcome is in agreement with the relative topicity observed for all 1,2-additions of nucleophiles to the CN bond of aldehyde SAMP-hydrazones.²⁶ The preferential formation of the S isomer can be explained considering an initial complexation of a first equivalent of lithio hetarene with the chiral auxiliary to give the chelate structure B. This should allow a low-energy pathway for the subsequent nucleophilic addition and moreover should result in the complete shielding of the Si-face of
the imine double bond. The relative topicity of the nucleophilic attack is then directed by steric interactions, resulting in a Re-face attack by a second equivalent of organometallic reagent.

In order to demonstrate the generality of our approach, we performed the nucleophilic 1,2-additions on a range of different aldehyde hydrazones. First experiments were conducted using 2-(thienyl)lithium as a nucleophile.

Scheme 2. Screening of different aldehyde SAMP-hydrazones: a) 2-(thienyl)lithium Et₂O or 1-methyl-2-lithiopyrrole, THF; b) THF, BH₃THF, reflux; c) CbzCl, K₂CO₃, THF/H₂O.

As depicted in Scheme 2, the application of our established 3-step protocol afforded in all cases the desired carbamates 5a–f in high overall yields and excellent enantiomeric excesses (Table 3). In particular, it is remarkable that in the addition steps the rates of formation of the tertiary hydrazines as well as the selectivities were not significantly altered by the presence of bulky groups on the hydrazone. A second series of experiments were conducted with 1-methyl-2-lithiopyrrole. In agreement with the observation made in our trial system, we found that although the desired carbamates 5g–j could be obtained with good to excellent selectivities, the overall yields were moderate. The decreased level of efficiency was mainly due to the insufficient conversion obtained in the first step, confirming the lower reactivity of 1-methyl-2-lithiopyrrole compared with 2-(thienyl)lithium.

Having demonstrated the generality and efficiency of our methodology, we turned our attention to exploring possible synthetic applications. For this purpose, as disclosed in the introduction, α-(2-furyl)alkylamines represented a straightforward entry into the synthesis of α-amino acids as the furan moiety is a synthetic equivalent of the carboxylic acid functionality. Intrigued by this possibility and confident that our methodology could provide a flexible solution, we decided to embark on an asymmetric synthesis of α-amino acids.

The reaction sequence to synthesize the benzoyl protected 2-furylalkylamines 7 is outlined in Scheme 3. The SAMP-hydrazones 2 were treated with 3.2 equiv of 2-(furyl)lithium in THF at –78 °C. NMR analysis of the crude products showed that the corresponding hydrazines were obtained with perfect stereocontrol. Although some of them were stable during flash chromatography and hence could be isolated, we found it more practical and efficient to carry out the protection on the crude hydrazine and to isolate the corresponding N-benzoyl hydrazines (Table 4).

Surprisingly, hydrazine 6e was obtained in very poor yield. Therefore, we chose to adopt a different pathway to introduce the methyl group by reacting hydrazone 2k with MeLi. When the reaction was performed in Et₂O, an excellent diastereoselectivity and high yield was obtained. Moreover, as expected, NMR analysis showed that (S,S)-6e and (S,R)-6e are epimers.
Table 3. Screening of different aldehyde SAMP-hydrazone 2 using 2-thienyllithium and 2-lithio-N-methylpyrrole as nucleophiles to form the amines 5 (see Scheme 2).

Thus we were able to confirm that by using only the SAMP chiral auxiliary we have access to both the enantiomers of α-(2-furyl)alkylamines. The N-N bond cleavage was achieved using the above-reported SmI_2-method, affording the N-protected amines in good to excellent yield and enantiomeric purity greater than 96% (Table 5). It is noteworthy that when compound 6f was used as substrate the corresponding amine 7f was obtained in 40% yield together with 20% of O-deprotected compound.

ᵃDetermined by chiral stationary phase HPLC.

Notably, product 8d demonstrated that our methodology is compatible with the SAMP-α-alkylation, allowing us to generate α-amino acids with 2 stereocenters.

A final detail should be addressed: regardless of the extensive experimentation we were not able to synthesize aromatic α-amino acids. Even by changing the solvent, temperature, and aromatic substituents the reaction between aromatic hydrazones and 2-furyllithium did not take place.

In summary, we have achieved a highly efficient asymmetric synthesis of α-(heteroaryl)alkylamines based on the nucleophilic 1,2-addition of lithiated aromatic heterocycles to aldehyde SAMP-/RAMP-hydrazones. In addition, oxidative furan to carboxylic acid conversion allowed the asymmetric synthesis of α-amino acids of high enantiomeric purities.

2. **Experimental**

Preparative column chromatography: Merck silica gel 60, particle size 0.040–0.063 mm (230–240 mesh, flash). Analytical TLC: silica gel 60 F254 plates from Merck, Darmstadt, Germany. Optical rotation values were measured on a PerkinElmer P241 polarimeter. Microanalyses were obtained with a Vario EL element analyzer. Mass spectra were acquired on a Finnigan SSQ7000 (CI 100 eV; EI 70 eV) spectrometer. IR spectra were taken on a PerkinElmer FT/IR 1760. ¹H and ¹³C NMR spectra were recorded on Varian Gemini 300 or Inova 400 spectrometers and all measurements were performed with tetramethylsilane as internal standard. Melting points were determined on a Tottoli melting point apparatus and are uncorrected. Gas chromatography: Lipodex A (Macherey-Nagel) or Chirasil-L-Val (25 m × 0.25 mm, 1 bar H₂, Chrompak) columns. ee-Determination with HPLC: Chiralpak AD or OD (250 × 4.4 mm, n-heptane: isopropanol = 95:5).

2.1. **General procedure 1 (GP1): preparation of the lithiated heteroarenes**

2-(Furyl)lithium: n-(butyl)lithium (6.4 mmol) was added to a solution of furan (462 mg, 6.8 mmol) in 20 mL of dry THF at 0 °C. The ice bath was removed and the mixture warmed up to 50–60 °C for 60–90 min.

2-(Thienyl)lithium, 2-(benzothienyl)lithium and 2-(benzofuryl)lithium: n-(butyl)lithium (6.4 mmol) was added to a solution of thiophene, benzothiophene, or benzofuran (6.8 mmol) in dry Et₂O (20 mL) at 0 °C. After 5 min the ice bath was removed and the mixture was stirred for 1 h at rt (90 min for benzothiophene).

2-Lithio-1-methyl pyrrole and 2-lithio-1-methylindole: n-(butyl)lithium (6.4 mmol) was added to a
solution of \(N\)-methylpyrrole or \(N\)-methylindole (6.8 mmol) in dry THF (20 mL) at rt. The mixture was warmed up to 60 \(^\circ\)C for 1 h or alternatively stirred at rt overnight.

2.2. GP2: synthesis of 1-(2-thienyl)alkylcarbamates
To a solution of 2-(thienyl)lithium in Et\(_2\)O cooled to \(-78\) \(^\circ\)C was added dropwise hydrazone 2 (2 mmol) dissolved in dry Et\(_2\)O (2 mL). After 30 min the cooling bath was removed, the temperature allowed to warm to room temperature, and the reaction mixture stirred for an additional 2–9 h. The mixture was quenched with saturated aqueous NH\(_4\)Cl and extracted 3 times with Et\(_2\)O. The organic layer was then washed twice with brine, dried over MgSO\(_4\), and evaporated in vacuo. The crude hydrazine was dissolved in dry THF (10 mL per mmol of hydrazine) and heated up to reflux with 10 or 20 equiv of BH\(_3\)-THF (1.0 mol in THF) for 9–36 h. The reaction was cooled to room temperature, acidified with aqueous HCl (1N), and stirred for 1 h. The THF was evaporated under reduced pressure and the aqueous solution was basified with a saturated solution of K\(_2\)CO\(_3\) and extracted with methylene chloride. The organic layers were concentrated in vacuo and the residue was dissolved in a mixture of H\(_2\)O and THF (1:1). Then 2 equiv of potassium carbonate were added, followed by 1.8 equiv of benzyl chloroformate, and the heterogeneous solution was stirred at room temperature overnight.

2.3. GP3: preparation of furfuryl hydrazines
To a solution of 2-(furyl)lithium (GP1) cooled to \(-78\) \(^\circ\)C was added dropwise hydrazone 2 (2 mmol) dissolved in dry THF (2 mL). After 30 min the cooling bath was removed and the temperature allowed to warm to rt, followed by stirring for an additional 2–18 h. The mixture was hydrolyzed with saturated aqueous NH\(_4\)Cl and extracted 3 times with Et\(_2\)O. The organic layer was then washed twice with brine, dried with MgSO\(_4\), and evaporated in vacuo. The crude product was either purified via column chromatography or used as crude product in the next step.

2.4. GP4: SmI\(_2\) promoted cleavage
To a solution of protected hydrazine in dry THF (strict anaerobic conditions are required) (10 mL per mmol of hydrazine) were added 2 equiv of DMPU followed by 2–3 equiv of SmI\(_2\). After 2 h at rt the reaction mixture was quenched with a mixture of NaHCO\(_3\) solution and CH\(_2\)Cl\(_2\) (5:2), extracted with CH\(_2\)Cl\(_2\), dried over MgSO\(_4\), and concentrated in vacuo. The crude product was purified by column chromatography.

2.5. GP5: oxidation of furfuryl amides to \(N\)-protected \(\alpha\)-amino acids
RuCl\(_3\)-H\(_2\)O (2 mol%) was added to a mixture of NaIO\(_4\) (15 equiv) in CH\(_2\)Cl\(_2\)/MeCN/H\(_2\)O (1.0:0.04:0.7) and the mixture was stirred for 0.5 h. A solution of furfuryl amide in CH\(_2\)Cl\(_2\) was rapidly added to the mixture via cannula. Upon completion of the reaction after 2 h, the organic phase was separated and the aqueous phase was washed with CH\(_2\)Cl\(_2\). The collected organic layers were washed with saturated aqueous NaHSO\(_3\) and brine, dried (MgSO\(_4\)), and concentrated in vacuo. The crude product was purified by column chromatography or recrystallization.
2.6. **(1S)-(1-Thiophen-2-yl-propyl)-carbamic acid benzyl ester (4a)**

Prepared according to GP 2 from 2-lithio-thiophene (6.4 mmol) and hydrazone 2a (340 mg, 2.0 mmol). After N,N-cleavage and protection purification by column chromatography (Et₂O:pentane 1:2) gave 4a (420 mg, 75%) as a colorless solid. ee ≥ 99%; mp 69–70 °C; [α]²⁶_D ~ 57.8 (c = 1.4, CHCl₃).

IR (KBr): ~ν = 3309, 2971, 2934, 2878, 1685, 1535, 1499, 1467, 1454, 1443, 1327, 1298, 1266, 1238, 1081, 1045, 1029, 974, 752 cm⁻¹.

1H NMR (400 MHz, CDCl₃): δ = 0.96 (t, 3H, J = 7.4 Hz, C₃H₃CH₂), 1.85–1.96 (m, 2H, CH₂CH₂), 4.91–5.14 (m, 4H, NH, CHNH, CH₂OC=O), 6.93–6.97 (m, 2H, arom CH), 7.18–7.20 (m, 1H, arom CH), 7.29–7.34 (m, 5H, arom CH) ppm.

13C NMR (100 MHz, CDCl₃): δ = 10.97 (C₃H₃), 30.49 (CH₃CH₂), 52.80 (CH₂OC=O), 124.31, 124.47, 126.98, 128.34, 128.73, (arom CH), 136.58, 146.18 (arom C), 155.83 (C=O) ppm.
