**Abstract:** A total of 169 species of macrofungi were determined in Samsun province between 1997 and 2001, of which 19 belonged to the *Ascomycota*, 149 to the *Basidiomycota* and one to the *Myxomycota*. Among these, 51 species were edible, 67 inedible, 28 edible but not worthwhile or best avoided because of possible confusion with poisonous species, and 12 species were poisonous. The edibility of 11 species was unknown.

**Key Words:** Macrofungi, mycoflora, taxonomy, Turkey

### Samsun İli Makromantarları

**Özet:** Samsun ilinde 1997-2001 yıllarında yapılan araştırmada, 19 adedi *Ascomycota*, 149 adedi *Basidiomycota* ve 1 adedi *Myxomycota* bölümlerine ait toplam 169 makromantar türü belirlenmiştir. Bunlardan 51'inin yenen, 67'sinin yenmeyen, 28'inin yenen fakat değersiz olan veya zehirli türlerle karıştırılabileceğinden sakınılması tavsiye edilen, 12'sinin ise zehirli tür olduğu saptanmıştır. 11 türün yenme durumu ise bilinmemektedir.

**Anahtar Sözcükler:** Makromantarlar, mikoflora, taksonomi, Türkiye

### Introduction

Macrofungi are important components of forest ecosystems. Although some cause white- or brown-rot on trees, most of them are ectomycorrhizal and are important for their mutualism, since they enhance nutrient uptake from the soil. In addition, with their high contents of minerals and vitamins, some edible species have nutritional value. The cultivated mushroom *Agaricus bisporus* (Lge.) Sing., a humicolous, non-mycorrhizal fungus, is one of the best known species in this group. Determining the mycobiota of a region is very important in order to catalogue potentially parasitic ones and effectively utilise the mycorrhizal and edible ones. A number of studies have been performed to determine the mycobiota of Turkey (Baytop, 1994; Mat, 1998) and a checklist of *Agaricales* found in Turkey was prepared by Sesli & Baydar (1996).

Samsun province has a rich mycobiota because of its mild climate and rich vegetation. In previous studies

conducted in the province, a total of 20 species were recorded, of which 13 are edible, four inedible and three poisonous (Niemala & Uotila, 1977; Watling & Gregory, 1977; Öder 1986; 1988; Gücin & Dülger, 1994; Sesli, 1999). There was no doubt that more species could be found in this area by detailed studies, and our previous studies increased the total number of macrofungus species to 91 (Hatat & Pekşen, 2000; Pekşen & Karaca, 2000). Since one of these papers related only to species of interest and the other to edible fungi, this paper lists all the macrofungi from the province collected between 1997 and 2001.

### Materials and Methods

In this study, fungi were collected during field trips carried out around Samsun in different seasons between 1997 and 2001. The habitat and morphological characteristics of the macrofungi found in various localities were recorded and the samples were

photographed for later identification. The microscopic features of the species were determined in the laboratory. The fungi were identified according to the relevant literature (Breitenbach & Kranzlin, 1984; Pacioni, 1985; Arora, 1986; Garnweidner, 1994; Phillips, 1994; Courtecuisse & Duhem, 1995; Bessette et al., 1997). Exsiccatae of the fungal samples were kept in the personal herbaria of the authors. Citations of the authors' names presented are standardised according to Kirk & Ansell (1992).

## Results

The species of macrofungi determined during the surveys performed in Samsun province between 1997 and 2001 are listed below. The localities, collection dates, edibility and herbarium numbers of the samples are also given. The taxonomic arrangement follows Ainsworth and Bisby's Dictionary of the Fungi, 8th ed. (Hawksworth et al., 1995).
