Abstract

In this work, the signal and noise behaviors of a microwave transistor within its operation domain (CT, V_{DS}, I_{DS}, f) are modeled by the Artificial Neural Network (ANN) and Fuzzy Logic System (FLS) without using any information on the microwave circuit theory. A worked example is presented where the same data is employed for both models selected from the manufacturer's data sheets. Performances of the FLS and ANN models are compared and conclusions are drawn.

Key Words: *Fuzzy Logic System (FLS), Artificial Neural Network (ANN) model, Signal and Noise parameters, Black-Box model*

1. Introduction

Optimization techniques developed within the last few decades facilitates to enlarge the differential bandwidth Δf of the equivalent circuit for a transistor to the whole operation bandwidth B at the chosen configuration type CT , bias condition V_{DS}, I_{DS} [1], [2], [3], [4]. These works are based on the optimization of the equivalent circuit elements by referring the measured Signal (-S) and Noise (-N) parameters as the target sets. Another alternative developed nowadays is the “Data –basis” model which is the ”Black-Box Soft –Model” resulted from application of the “Soft –Computing” techniques [5], [6], [7].

In this paper ,the ”Black-Box Soft –Model” for a microwave transistor is worked out using the fuzzy logic and neural network techniques as the “Soft Computing” techniques, which are the popular techniques recently utilized in the microwave world [8], [9].

The ”Black-Box Soft –Model” is given in the Fig. 1 whose inputs are the operation parameters CT, V_{DS}, I_{DS}, f and outputs are the scattering [S] and noise [N] parameters. The data pairs in the frequency subdomain of the device operation domain (CT, V_{DS}, I_{DS}, f) are in the form:

$$\begin{bmatrix} f_1 & S_1^{(1)} & S_2^{(1)} & \dots & S_p^{(1)} & S_1^{(1)} & S_2^{(1)} & \dots & S_q^{(1)} \\ f_1 & S_1^{(2)} & S_2^{(2)} & \dots & S_p^{(2)} & S_1^{(2)} & S_2^{(2)} & \dots & S_q^{(2)} \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ f_1 & S_1^{(N)} & S_2^{(N)} & \dots & S_p^{(N)} & S_1^{(N)} & S_2^{(N)} & \dots & S_q^{(N)} \end{bmatrix} \quad (1)$$

where $S^{(k)}$ and $N^{(k)}$ are vectors given at a sample frequency as follows:

$$[S^{(k)}] = [|S_{11}|^{(k)} \varphi_{11}^{(k)} |S_{12}|^{(k)} \varphi_{12}^{(k)} |S_{21}|^{(k)} \varphi_{21}^{(k)} |S_{22}|^{(k)} \varphi_{21}^{(k)}] \quad (2)$$

$$[N^{(k)}] = [F_{\min}^{(k)} \quad |\Gamma_{\min}|^{(k)} \varphi_{\min}^{(k)} \quad R_N^{(k)}] \quad (3)$$

In order to design the soft model, we divide the data pairs into the two different parts, one to build the soft model and, the other to check the validity of the model function. We call the former *training data pairs*, and the latter *checking data pairs*. Using the training data pairs, we obtain the network parameters of the model. The data pairs are obtained from the Manufacturer’s Data Sheets of the utilized transistor.

Figure 1. The “Black-Box Soft –Model” of a microwave transistor.

As far as the device modeling is concerned, both the Fuzzy Logic (FLS) and Artificial Neural Systems (ANN) can be considered as a universal function predictor, with the extra capability of incorporating the human expert information. Fuzzy and neural network models are given in section II and III in details, respectively.

2. Fuzzy Logic System

Fuzzy logic was firstly worked out by Lütfi A. Zadeh in 1965 in [10]. Since then it has been used in many interesting applications replacing “Aristo” logic. There are three key phases of any fuzzy logic process: Justification, inferencing and defuzzification. Inferencing and defuzzification are the key processing phases that characterize the performance of the implementation. For any arbitrary fuzzy system, there are three fundamental number representation issues to consider: Representation of the input variables, the output variables and the internal (truth) values. In each case a binary numbering scheme is assumed and simple manipulation can be applied to limit values to lie within positive number range. In our case, the input variables are the operation parameters of the active device, which are the configuration type CT, bias condition V_{DS} , I_{DS} and operation frequency f , and the output variables are Scattering and Noise parameters, all of which is totally 12 functions (Figure 2). Fuzzification is simply the mapping of an input or output value to a membership function set. Assuming the membership function is stored as values in a continuous memory block then fuzzification can be viewed as a simple “Lookup Table” operation. Lookup tables have the fundamental advantage that any arbitrary shape function can be stored. The data word length of the input variable will define the height of the table whilst the data word length of the output result will define its width.

Figure 2. Fuzzy Model for a microwave transistor.

Lookup table methods do generally lead to very large storage requirements where large numbers of membership functions with large numbers of fuzzy rules and multiple inputs are used. Typical memberships for the input parameters are given for I_{DS} and f in Figure 3. Inferencing takes the truth values generated during the fuzzification process and applies the “Fuzzy” rules associated with them using the fuzzy logic operators. These rules answer the question of in which fuzzy sets Scattering and Noise parameters must have memberships, by considering the memberships of their frequency and I_{DS} parameters in these sets.

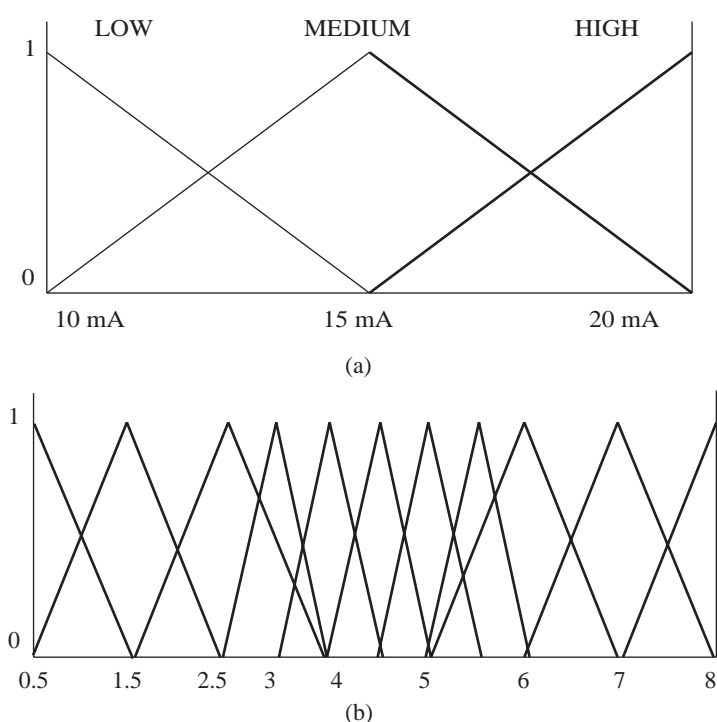

Figure 3. Membership functions for the inputs (a) I_{DS} (b) frequency f .

As an example for a rule given in the “Fuzzy” rule table can be described as follows:
 IF frequency \equiv VL AND $I_{DS} \equiv$ M THEN S_{11} Mag \equiv VH AND S_{11} Angle \equiv H AND

$$S_{12} \text{ Mag} \equiv \text{VL AND } S_{12} \text{ Angle} \equiv \text{VH} \tag{4}$$

As it can be seen from these verbal expressions above, every rule describes the fuzzy relation between fuzzified input and output variable sets. After all the rules are processed - and fuzzified results are obtained which have to be defuzzificated to obtain the real output – input relations. Defuzzification process is preformed in ‘defuzzification’ unit of fuzzy controller [11]. In this work, ‘Altitude Method’ is employed in defuzzification process which uses ‘The Biggest Membership Principle’. A worked example will be presented in the forth section.

3. Artificial Neural Network Model

Optimization and simulation microwave circuits require reliable and efficient models. The models based on classical electromagnetic methods are very complex and time-consuming. Moreover, finite simple models usually used in microwave circuit simulators have limitations. Recently, neural network approached models have gained attention for their fast and flexible algorithm specialty.

A neural network is a general mathematical computing paradigm that models the operations of biological neural systems. In 1943, McCulloch, a neurobiologist, and Pitts, a statistician, published a seminal paper titled “A logical calculus of ideas imminent in nervous activity” [12]. At approximately the same time, Frank Rosenblatt was also motivated by this paper to investigate the computation of the eye, which eventually led to the first generation of neural networks, known as the perceptron [13].

A neural network has at least two physical components, namely, the processing elements and the connections between them. The basic processing elements are called neurons, and the connections between the neurons are known as links. Every link has a weight parameter associated with it. Each neuron receives stimulus from the neighboring neurons connected to it, processes the information, and produces an output. Neurons that receive stimuli from outside the network are called input neurons. Neurons whose outputs are used externally are called output neurons. Neurons that receive stimuli from other neurons and whose output is a stimulus for other neurons in the neural network are known as hidden neurons. There are different ways in which information can be processed by a neuron, and different ways of connecting the neurons to one another. Different neural network structures can be constructed by using different processing elements and by the specific manner in which they are connected [14]. In figure 4, it is shown that basic neuron structure: w_n is weight of link n , $f(u)$ is its activation function for transferring.

Figure 4. Structure of a basic neuron.

Multilayer perceptrons (MLP) are the most popular type of neural networks in use today. They belong to a general class of structures called feed-forward neural networks, a basic type of neural network capable of approximating generic classes of functions, including continuous and integrable functions [14]. MLP neural networks have been used in a variety of microwave modeling and optimization problems. In this work, the MLP network –shown in figure 5- is used for black-box modeling of signal and noise parameters.

In this work, hidden layer neurons’ activation function has been chosen sigmoid, input and output has been linear also. Sigmoid function is good enough for modeling [5, 6]. The method of conjugate gradient has been chosen for fast training. This method originally derived from quadratic minimization, in which the objective function E_T , can be efficiently found within N iterations. With initial gradient $g_{init} = \frac{\partial E_T}{\partial w} |_{w=w_{init}}$, and direction vector $h_{init} = -g_{init}$, the conjugate gradient constructs two vector sequences

$$g_{k+1} = h_k + \lambda_k H h_k \quad (5)$$

$$h_{k+1} = -g_{k+1} + \gamma_k H h_k \quad (6)$$

are taken and

$$\lambda_k = \frac{g_k^T g_k}{h_k^T H h_k} \quad (7)$$

$$\gamma_k = \frac{g_{k+1}^T g_{k+1}}{g_k^T g_k} \text{ or } \gamma_k = \frac{(g_{k+1} - g_k)^T \cdot g_{k+1}}{g_k^T g_k} \quad (8)$$

where \mathbf{h} is the conjugate direction and \mathbf{H} is the Hessian matrix of the objective function E_T . Here, (7) is called the Fletcher-Reeves formula and (8) is called the Polak-Ribiere formula. In this method, the descent

direction runs along the conjugate direction, which can be accumulated without matrix computations [14]. The conjugate direction in a two dimensional weight space is shown in Figure 6.

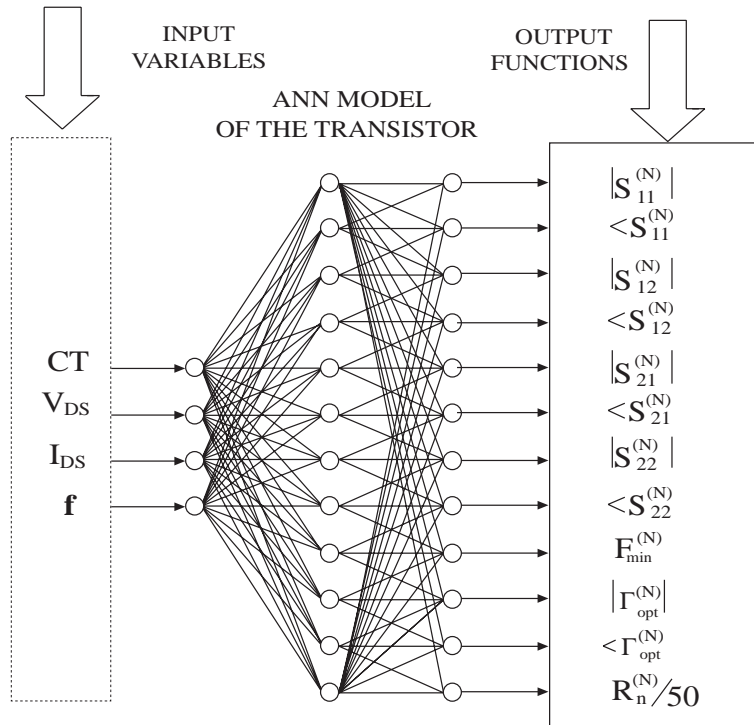

Figure 5. Neural Network Model of a microwave transistor.

Figure 6. Illustration of conjugate direction in a two-dimensional weight space assuming in an ideal Quadratic Error Surface.

4. Simulation and Conclusion

In this work, ANN and FLS models are completed for Agilent’s ATF21186 transistor, the resulted typical characteristics are given in the Figure 7a, 7b, 7c, 7d, 7e and 7f where for a fixed $V_{DS}=2V$, I_{DS} can vary from 10mA to 20mA and f varies along the whole operation bandwidth. Furthermore the results given in the Table with the corresponding manufacturer’s values . It can be concluded that all predicted variables by the two models are good agreement with the target values.

Table Calculated results of the Fuzzy and the ANN Model of ATF-21186 with catalogue data.

In this study, both the ANN and FLS are utilized as the universal function predictor in the modeling of a microwave transistor. In the other words, using “N” known sample points in the operation domain of the device, the whole signal and noise behavior is approximated with a great accuracy in the operation domain. So the “Black-Box Soft –Model” is achieved for a small signal microwave transistor for the design purpose of the active microwave device and circuits.
